

Q.1 → parametrization is the process of running the same test cases with multiple sets of input data to validate different scenarios without rewriting the test script.

Q.2 →

- i] store input data in external sources (Excel, CSV, databases or JSON).
- ii] configure the automation tool to read data dynamically.
- iii] execute the test iteratively for each data set, comparing actual vs expected outputs.

Q.3 →

- i] detects and manages unexpected errors or implicit crashes during test execution.
- ii] ensure the test continues running or fails gracefully instead of stopping abruptly.

Q.4 →

- i] prevents abrupt termination of test execution.
- ii] provides meaningful error logs for debugging.
- iii] ensure consistent result across multiple test runs even if some error occur.

Q.5 →

- i] use robust input validation for all parametrized data.

ii] wrap test steps in try-catch or equivalent exception handling blocks.

iii] log detailed errors including input data causing failure.

iv] Design tests to continue execution for remaining data sets despite exceptions.

v] maintain modular test to separate test logic from data and error handling.
